

# Image processing

„object“

image

perception,  
processing

Where?

eg. radiology, pathology, endoscopy ..... and in the normal life.

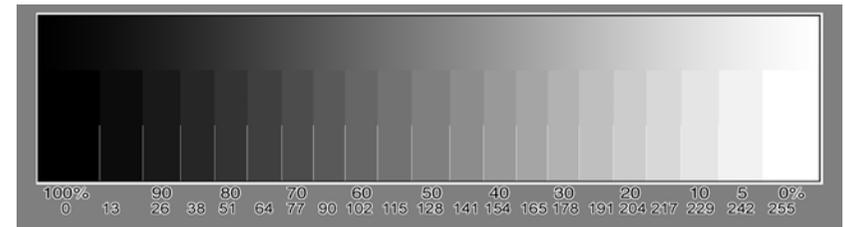

# Image

	analogue	digital
pixel size	random	uniform
pixel distance	random	uniform

grayscale (8-bit):

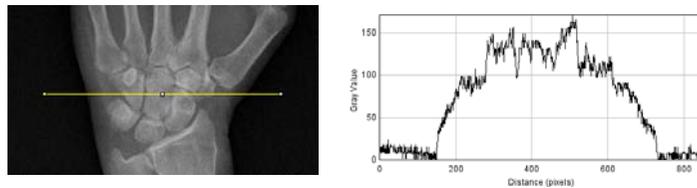

- „0“: black
- „255“: white

Color image: R (red),  
G (green) and B (blue)  
channels additive  
combination  $2^{24}$ ,  
about 16 million  
colors.

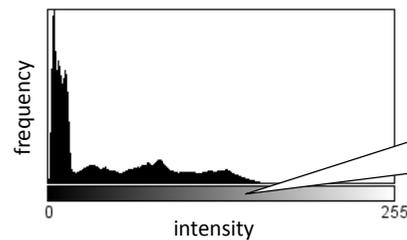

# Intensity-histogram

The different colors (intensities) may be plotted as functions:

Histogram: The frequency of the colors ordered to the pixels in the whole image or in its selected part:

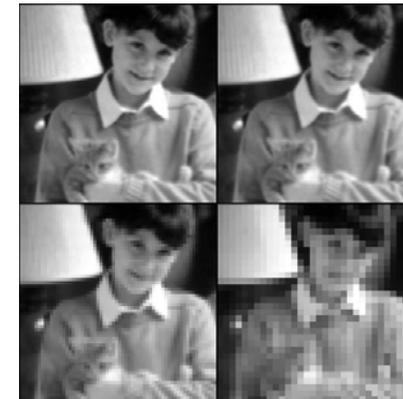

The dark tone is dominant  
in the image on the base of  
the intensity distribution.  
The whole intensity range is  
not used!

# Resolution

The reciprok of the resolution limit

- PPI (pixels per inch - display)
- DPI (dots per inch - printer)
- line pair / cm

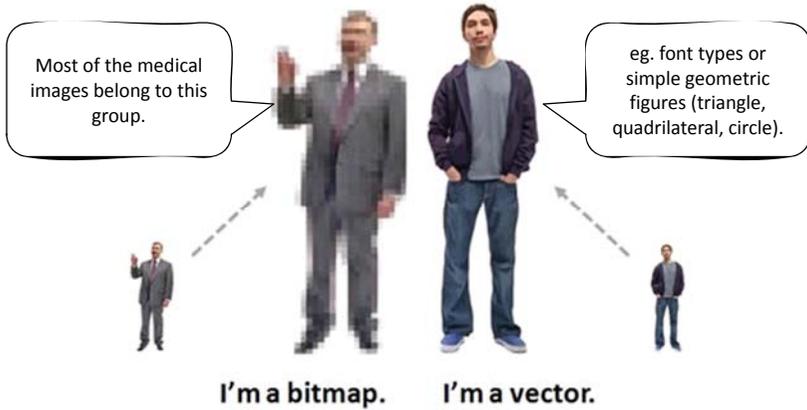

Decreasing resolution:  
**loss of information**,  
subsequent increase  
of resolution:  
**no more information!**

# Zoom

Increasing pixel size.

**Bitmap**: Zoom is convenient to the processing, but there is no more information.

**Vector graphics**: unlimited zoom, but must be described as curves.

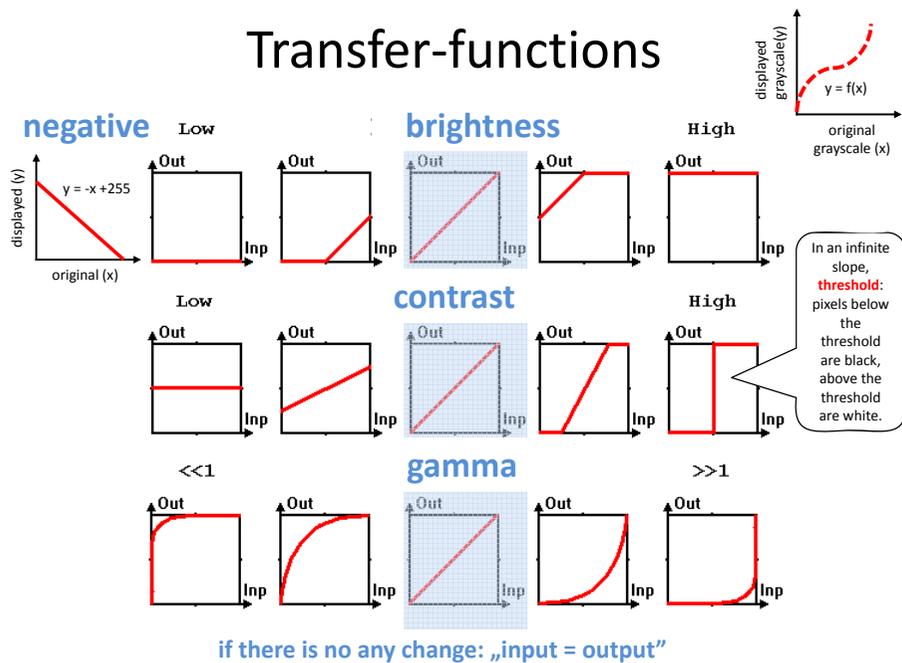

# Addition / Subtraction

DSA = Digital Subtraction Angiography

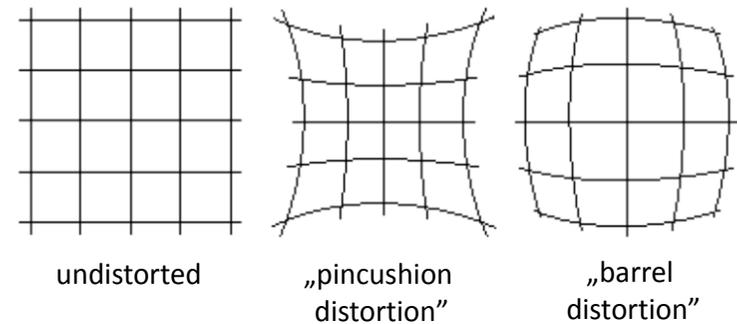

(The subtraction of the grayscale values in the case of each pixels in the whole image)

# Transfer-functions

# Distortion

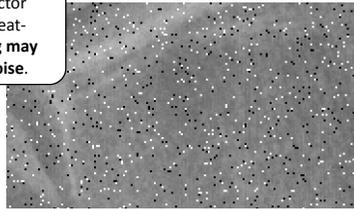

It applies if a 3D structure (eg. organ) is displayed in 2D.

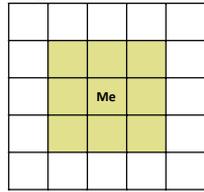

# Noise:

- most common source: detector
- pepper and salt noise (random black and white pixels)

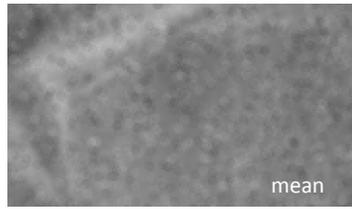

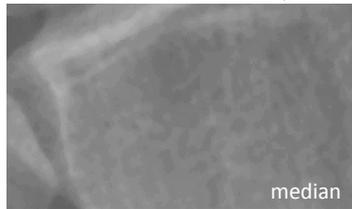

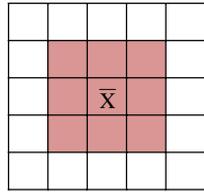

The semiconductor detectors are heat-sensitive: cooling may decrease the noise.

# Filtering:

Effective in the case of pepper and salt noise.

# Fourier-principle

Every periodic signal may be generated as the sum of sinusoidal functions.

**time function**

$$y(t) = \sum_k a_k \sin(k \cdot \omega_0 \cdot t + \Phi_k)$$

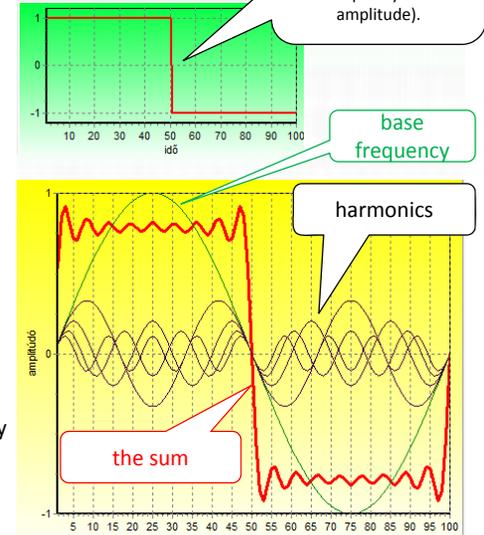

FT  $\downarrow$   $\uparrow$  inverz-FT

**frequency function**

1D:  $f(x) \leftrightarrow F(u)$  spatial frequency

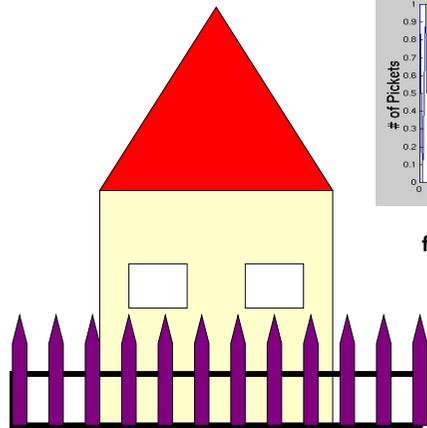

2D:  $f(x,y) \leftrightarrow F(u,v)$  2D spatial frequency

image is a 2D...

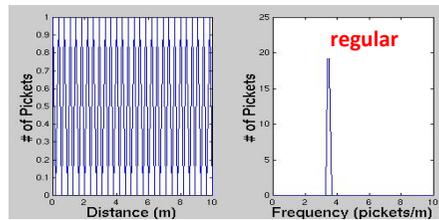

# Fourier transformation (FT)

(spatial domain  $\rightarrow$  frequency domain)

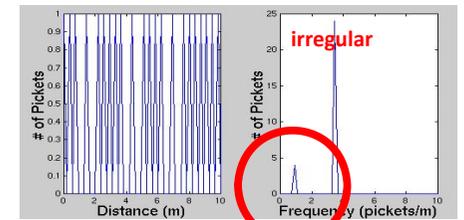

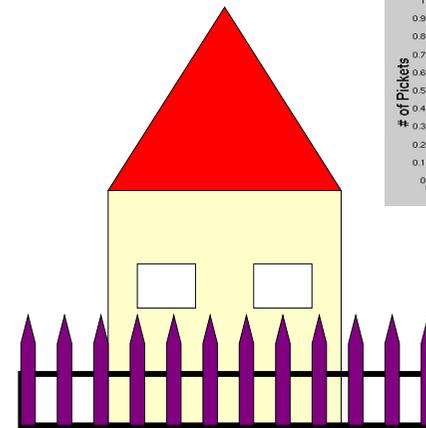

spatial domain (house and fences)

frequency domain (repeating fences)

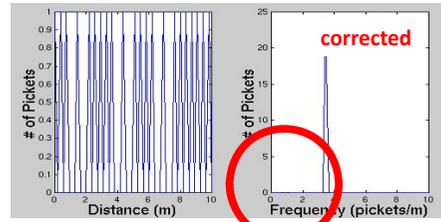

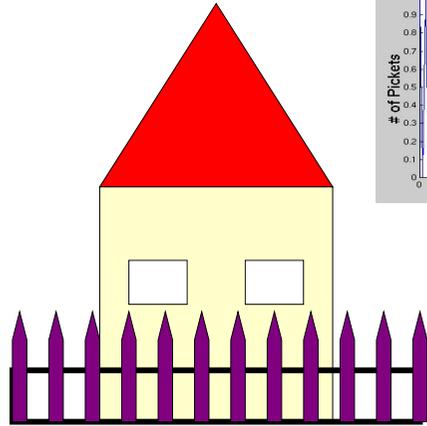

# Fourier transformation (FT)

(spatial domain  $\rightarrow$  frequency domain)

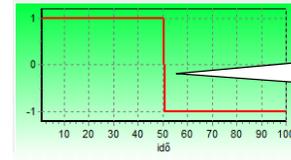

# Fourier reconstruction

(frequency domain → spatial domain)

Application of the Fourier-transformation :  
a) **noise filtering**

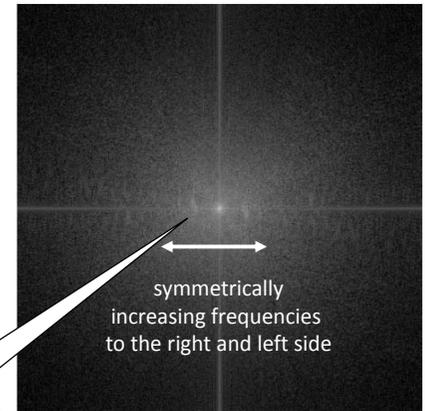

The sharp changes in the image may be described exactly by high frequency components.

image

striated pattern as a periodic „square pulse”

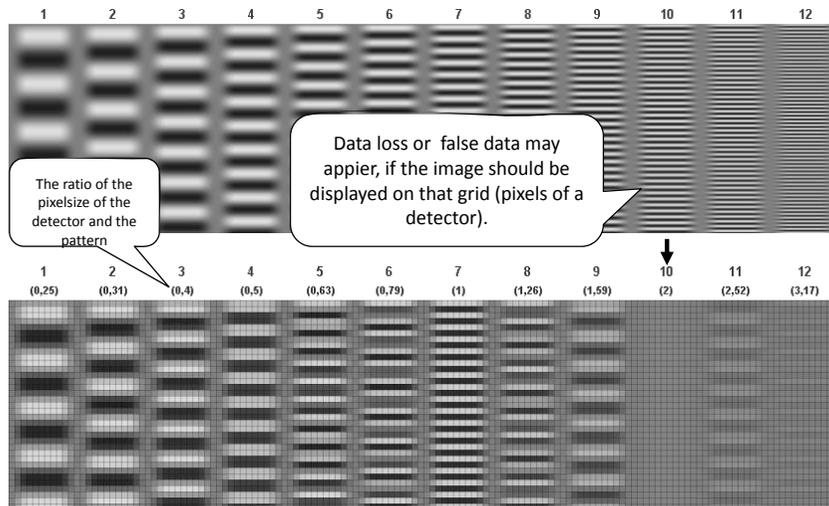

symmetrically increasing frequencies to the right and left side

Fourier transformation

Fourier-transformation :  
b) **to find edges**

# Aliasing (sampling problem)

The sampling frequency must be the double of the signal frequency at least!

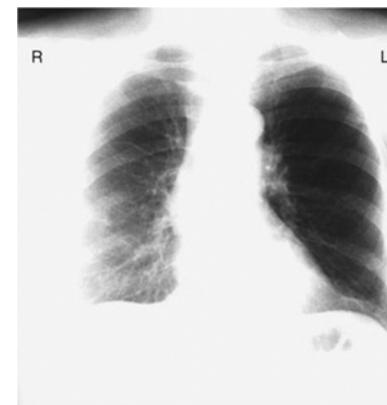

# Moiré

overexposed

underexposed

left side mastectomy

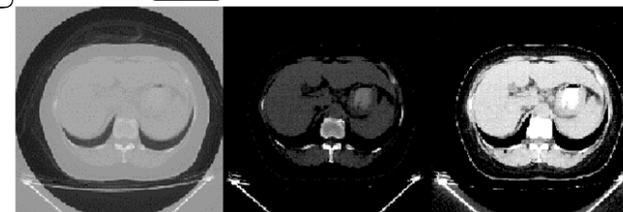

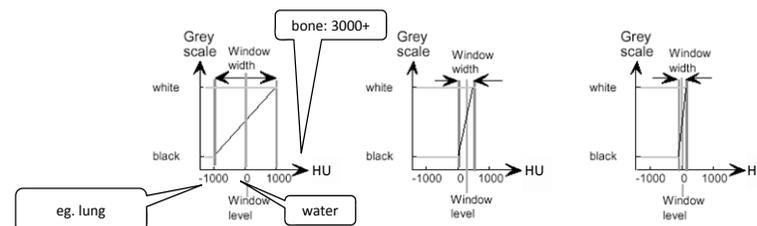

nipples

## Windowing

as a transfer function

$$HU = \frac{\mu_x - \mu_{water}}{\mu_{water}} \cdot 1000 \quad \mu: \text{linear attenuation coefficient}$$

# File types

- **uncompressed**, eg. BMP (bitmap)

- **compressed**

- **Lossless**, eg. TIFF, GIF
- **Lossy**, eg. JPG

small storage requirements, but a part of the information content loses

- **DICOM**

- image (or series of images)
- patient data
- Data on imaging mode / settings of the equipment, windowing, radiation dose in the case of CT, etc.

„Digital Imaging Communications in Medicine“  
(uniform file type + network communication protocol)
