

Transport processes-1

fluid flow

28/03/2024

Dora Haluszka

Transport = translocation of materials

biological significance: intracellular, intercellular, and transmembrane flow of matter (breathing, blood circulation, transport across membranes, metabolism)

Distinct transport mechanisms:

- Transport is due to a collective, directional motion of particles, such as in a **fluid flow**
- Transport is due to independent random motion of particles, such as **diffusion**
- Transporting materials through lipid bilayers – **membrane transport**

Macroscopically observable fluid flow

(direction of tangent = direction of velocity
density of streamlines = magnitude of velocity)

Small drag in streamlined position

Large drag in unstreamlined position

Flow in rigid-wall tubes

Volumetric flow rate (I_V):

$$I_V = \frac{DV}{Dt} = A \frac{Ds}{Dt} = A\bar{v}$$

Stacionary flow

parameters of flow are **constant** in time

Continuity principle: in a stacionary flow the volumetric flow rate is constant

e.g. law of mass balance for incompressible fluids (gases?)

$$A_1 v_1 = A_2 v_2 = \text{constant}$$

A = cross-sectional area

v = flow velocity

Viscosity – internal friction

F = shear force
 A = area of fluid layer
 η = viscosity
 v = flow velocity
 y = distance between fluid layers
 F/A = shear stress (τ)
 $\Delta v/\Delta y$ = velocity gradient (D)

$$\frac{F}{A} = \eta \frac{Dv}{Dy} \quad (\text{Newton's friction law})$$

$$\eta = \frac{\tau}{D}$$

Units of viscosity: $1 \text{ Pas} = 1 \frac{\text{Ns}}{\text{m}^2} = 10 \text{ P}(\text{poise})$

Viscosity of distilled water (25 °C): 1 mPas (1 centipoise)

Types of fluids based on viscosity

1. *Ideal*

frictionless, incompressible

$\rho = \text{constant}$, $\eta = 0$

2. *Non-ideal (real)*

a. *Newtonian (viscous)*

η independent of shear stress

b. *Non-newtonian (anomalous)*

η changes with shear stress

$$\eta = \tau / D$$

Viscosity – internal friction

substance	η (mPa·s) 20 °C
air	(101 kPa) 0.019
water	1
ethanol	1.2
blood (37 °C)	2–8
glycerine	1490
honey	2000–14000

viscosity of gases increases with rising temperature

viscosity of fluids decreases with rising temperature

$$\eta \sim e^{\frac{E}{kT}}$$

$$\frac{F}{A} = \eta \frac{Dv}{Dy}$$

Fluids obeying the above equation are called **newtonian fluids**.

Friction on spherical particles – Stokes law

Georg Gabriel Stokes
(1819-1903)

Frictional force is proportional with the velocity:

F = force

γ = drag coefficient (shape factor)

v = flow rate

r = radius of sphere

η = viscosity

$$F = \gamma v = 6\pi\eta r v$$

Types of flow:

laminar flow – fluid layers do not mix

turbulent flow – layers are mixing (chaotic streamlines)

*laminar
flow*

*turbulent
flow*

parabolic velocity profile

Osborne Reynolds
(1842-1912)

Reynolds number (Re):

$$Re = \frac{vr}{h}$$

v = flow rate (m/s)
 r = tube radius (m)
 ρ = density of fluid (kg/m³)
 η = viscosity (Ns/m²)

Re > 1000 – turbulent flow appears

Bernoulli's law

conservation of energy in ideal fluids

Daniel Bernoulli
(1700-1782)

$$p + \frac{1}{2} \rho v^2 + \rho gh = \text{const}$$

p = static pressure

$\frac{1}{2} \rho v^2$ = dynamic pressure

ρgh = hydrostatic pressure

Giovanni Battista
Venturi
(1746-1822)

Static pressure drops at the
tube narrowing

Applications: sprayer, atomizer, aspirator (vacuum pump), inspirator (Bunsen burner), diffuser, jet engine, wing profile, vacuum cleaner, biphasic pulse in aorta insufficiency

Hagen-Poiseuille's law

stationary laminar flow of newtonian fluids and gases in rigid-wall tubes

G.H.L. Hagen
(1797-1884)

J.-L.-M. Poiseuille
(1799-1869)

V = volume
 t = time
 R = tube radius
 η = viscosity
 p = pressure
 x = tube length

$V/t = I_V$ = volumetric flow rate
 $\Delta p/\Delta x$ = pressure gradient,
 maintained by $p_2 - p_1$ (negative!)
 A = cross-sectional area of tube
 I_V = volumetric flow rate

$$I_V = \frac{V}{t} = - \frac{R^4 \rho}{8h} \frac{Dp}{Dx}$$

$$I_V = - \frac{R^4 \rho}{8h D x} Dp \Rightarrow - Dp = R_{tube} \cdot I_V \Rightarrow U = R \cdot I$$

$1/R_{tube}$

Ohm's law!

Electric model of the arterial vascular system

$$\text{volume flow rate } (I_V) = \frac{\text{pressure drop } (\Delta p)}{\text{resistance to flow } (R_{\text{flow}})}$$

$$\text{electric current } (I) = \frac{\text{voltage } (U)}{\text{resistance } (R)}$$

static pressure drop (Δp)

electric voltage, potential drop (U)

resistance to flow (R_{flow})

resistance (R)

volume flow rate (I_V)

electric current (I)

Medical significance of fluid flow laws

Bernoulli's law:

Formation of aneurysm (pathological expansion of blood vessel):

- Expansion of vessel: diameter increases
- Flow rate decreases, according to continuity equation
- Static pressure increases due to Bernoulli's law
- Aneurysm pregreduates - positive feedback mechanism leading to catastrophe

Hagen-Poiseuille's law:

$$\frac{V}{t} = \frac{R^4 \pi \Delta p}{8\eta \Delta x}$$

Flow intensity, hence the delivered oxygen quantity, may be **drastically**

reduced in certain pathological conditions:

- constriction of blood vessels (e.g., diabetes, B rger's disease)
- change in blood viscosity (e.g., fever, anaemia)
- Reduction of vessel diameter by half leads to a reduction of volumetric flow by 1/16!

Medical significance of fluid flow laws

regulation of the intensity of blood flow
(Hagen-Poiseuille's law)

$$I_V = \frac{V}{t} = - \frac{R^4 \rho}{8h} \frac{Dp}{Dx}$$

Physiological regulation of the blood flow depending on the needs of tissues/organs

Flow parameters in the circulation

Flow conditions in the arterial system: pulsatile flow, elastic arterial wall

Flow conditions in the arterial system: pulsatile flow, elastic arterial wall

Viscosity of blood

55-60% of body mass is water 42 kg (70 kg body mass)		
2/3 intracellular 28 kg	1/3 extracellular 14 kg	
	1/3 plasma 4-5 kg	2/3 intersticium 9-10 kg

Blood: Average volume: 5 l
Average viscosity: 5 mPas
Average density: 1.05 g/cm³
Composition: 40-45 % corpuscular, 55-60 % plasma

Viscosity of blood

I. Hematocrit (htc , ϕ):

$$htc = \frac{V_{cells}}{V_{total}}$$

Normal range: 0.4-0.5.

Viscosity of blood as suspension
(in the physiologically relevant htc range):

$$\lg \eta_s = A + B\phi$$

η_s =suspension viscosity
A, B=empirical constants

Viscosity of blood

2. Plasma viscosity

- Depends on plasma proteins.
- In *paraproteinaemias* (e.g. myeloma multiplex or plasmocytoma) the concentration of immunoglobulins is high, leading to increased viscosity.

Plasma protein	Normal concentration	% ratio	Function
Albumin	35-50 g/l	55%	maintenance of colloind osmotic pressure, transport
Globulins	20-25 g/l	38%	Part of the immune system
Fibrinogen	2-4.5 g/l	7%	Blood coagulation

Viscosity of blood

3. *Plasticity of red blood cells*

- 65% suspension of blood-cell-size particles is rock hard.
- By contrast, a 95% blood suspension is fluid, with viscosity of ~ 20 mPas!
- Deformation of red blood cells: droplet, parachute, arrowhead shapes.

Disk-shaped cells with 7-11 μm diameter

Viscosity of blood

4. Aggregation of red blood cells

- Stack or rouleaux formation.
- More pronounced at low flow rates

Rouleaux (stack)

5. Flow rate, velocity gradient

Viscosity of blood

6. Blood vessel diameter

- With a decrease of vessel diameter, the anomalous (non-newtonian) behavior of blood becomes more pronounced.
- *Axial migration*: the red blood cells line up in the axis of the vessel (Bernoulli's law). In the axis the velocity gradient decreases, and near the vessel wall it increases. Increase in velocity gradient decreases apparent viscosity (Fåhræus-Lindquist effect).

Adaptation of RBC due to deformability

- Individual X at rest
- Individual X after 10 km running
- ▲ Individual X after a maximal treadmill test of 15'
- ▼ Individual X after a maximal cycling test of 15'
