

Generation of light - Light sources

Black-body radiation

Luminescence

Laser

Luminescence

Repetition

Types of energy states in atoms and molecules are independent
(not coupled)

Energy states are non-continuous, but discrete

Transition between states involves packets (quanta) of energy)

$$E_{total} = E_e + E_v + E_r$$

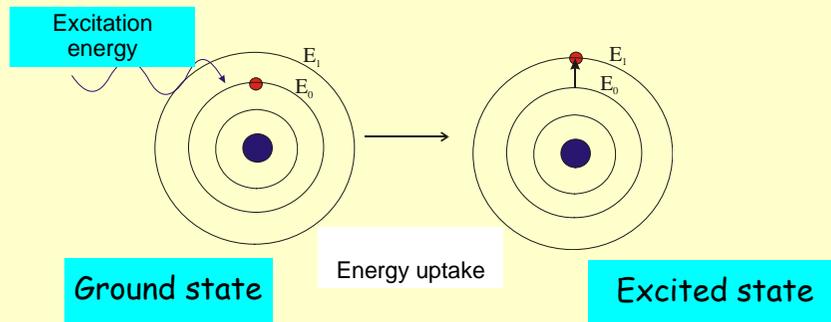

Scales of transition energies between different states are different:

$$E_e > E_v > E_r$$

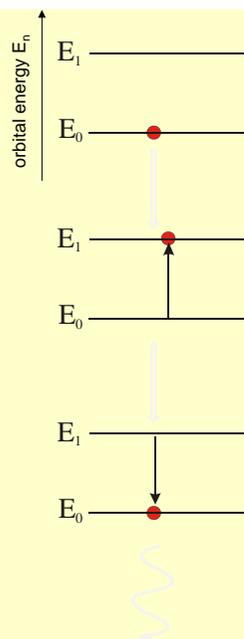

Consider a single atom

- Energy states are discrete
- Electrons occupy the lowest possible energy state (ground state)
- Pauli exclusion principle: no two identical fermions (particles with half-integer spin) may occupy the same quantum state simultaneously

Excitation modes

- absorption of radiation (UV/VIS) : *photoluminescence*
- chemical reaction: *chemo/bio-luminescence*
- Injection of charges: *electroluminescence*
- friction (mechanical deformation): *triboluminescence*
- thermally activated ion recombination: *thermoluminescence*
- Sound waves: *sonoluminescence*

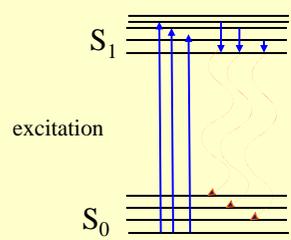

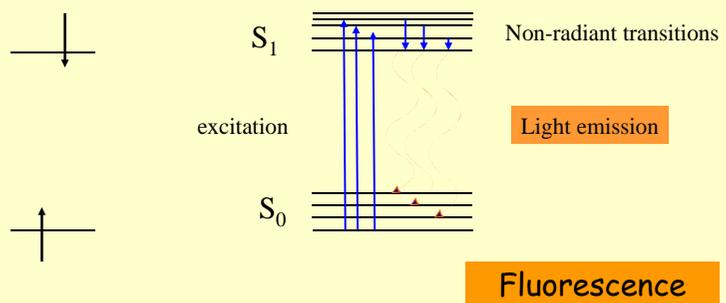

$$hf = E_1 - E_0$$

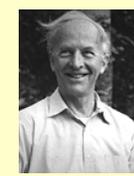

Luminescence: spontaneous light photon emission by electrons when they return from their excited state to their original (ground) state of lower energy

$$hf = E_1 - E_0$$

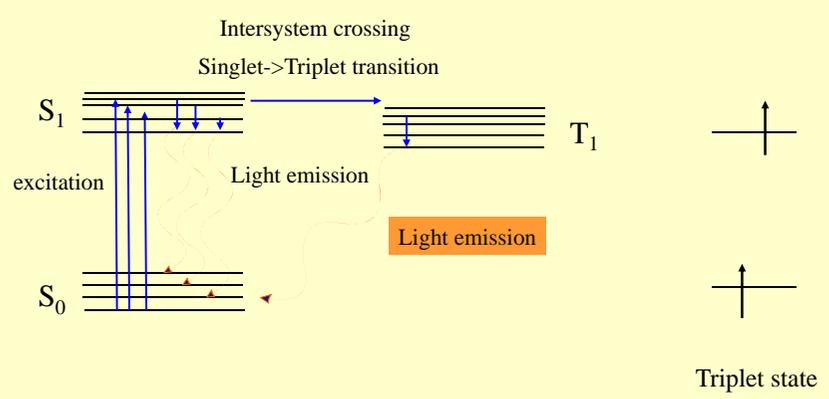

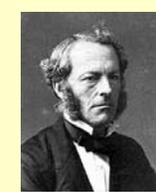

The energy of the electronic orbitals in molecules is perturbed by the discrete states of molecular vibrations

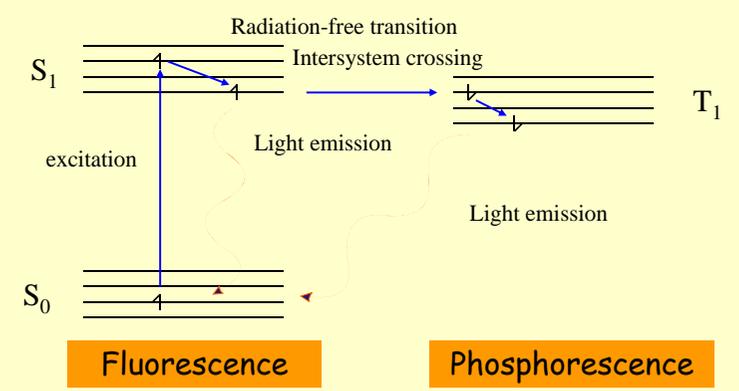

Kasha's rule:

Stokes-shift

Emitted photon energies

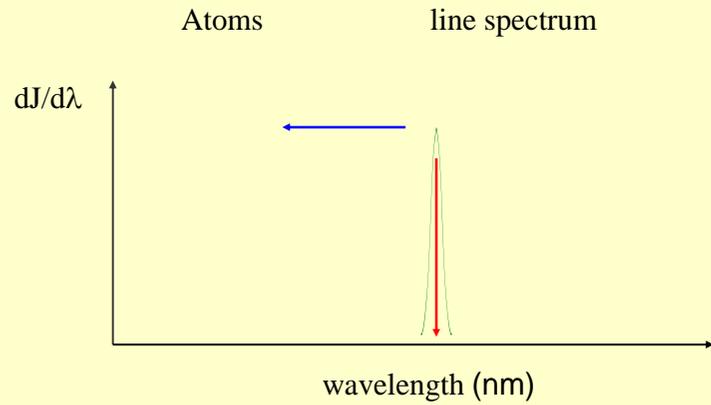

Stokes-shift

Characteristics of emitted light

Wavelength distribution of emitted light

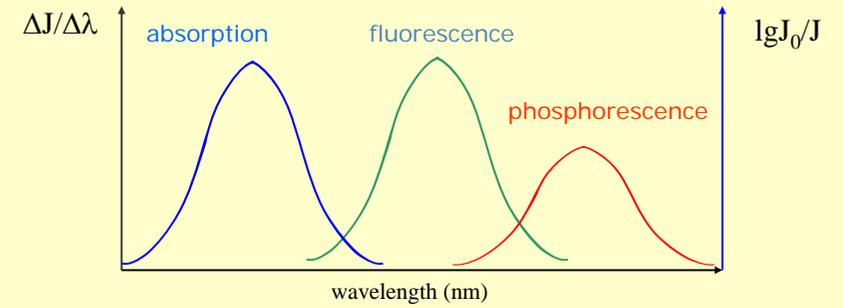

Emission spectrum

Wavelength distribution of emitted light

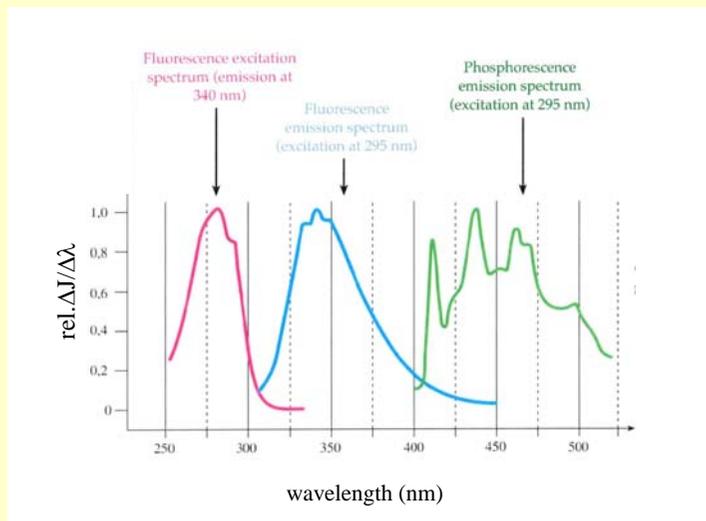

Emission spectrum

molecules: band spectrum

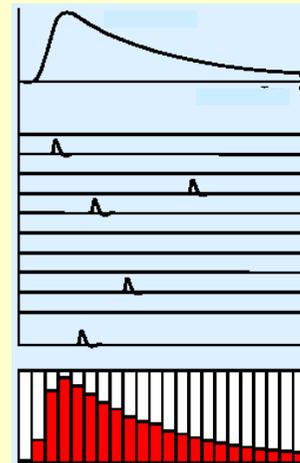

Stokes shift

E.g.: Corresponding spectra of triptophane

Excited-state lifetime

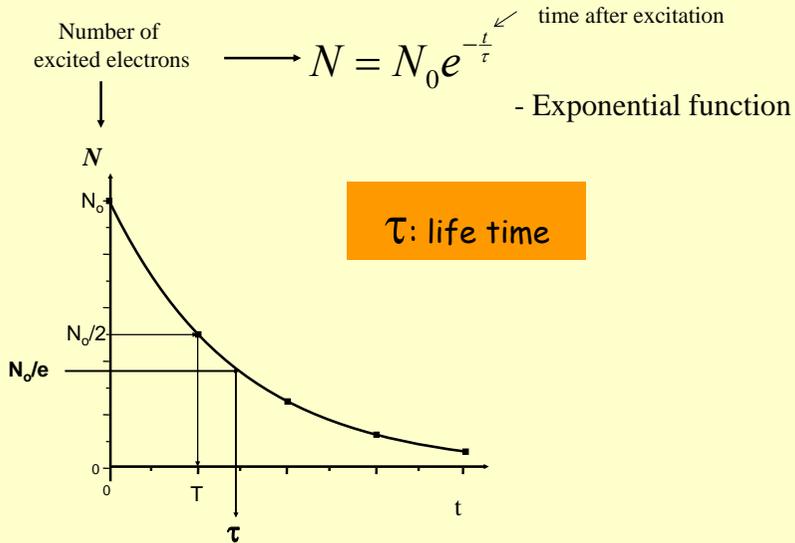

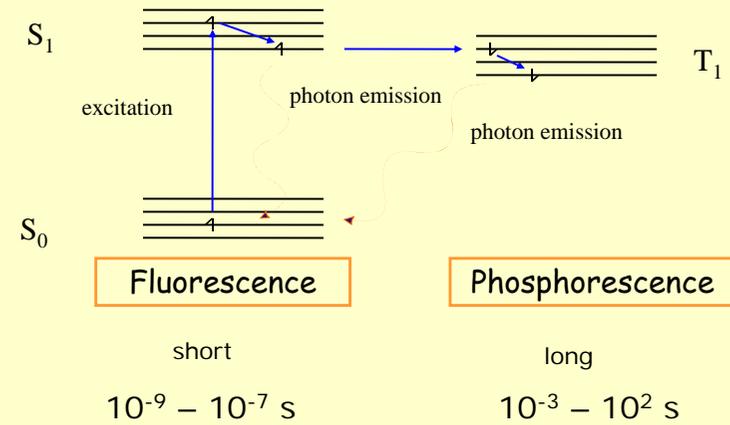

Single photon counting

Typical excited-state lifetimes

Lifetime

the time during which the number of excited electrons decreases to its e^{th} .

Is excitation always followed by photon emission?

Excited state decay can be caused by mechanisms other than photon emission and are therefore often called "non-radiative rates,,"

These can include: chemical reaction, dynamic collisional quenching, near-field dipole-dipole interaction, internal conversion and intersystem crossing.

Is excitation always followed by photon emission?

Quantum yield

Reciprocal of the number of absorbed photons for one photon emission

Fluorescence quantum yield (Q_F)

$$Q_F = \frac{\text{number of photons emitted}}{\text{numbe of photons absorbed}}$$

$$Q_F \leq 1$$

Types of luminescence

- fluorescence
- phosphorescence

They can be characterized by
emission spectrum

- types
- position of peaks
- amplitude

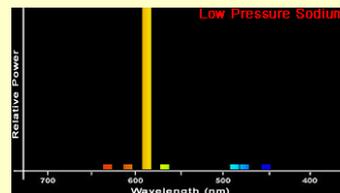

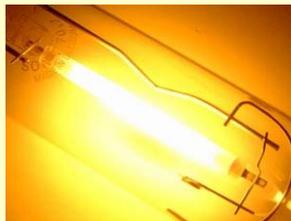

- lifetime
- quantum yield

Application fields of luminescence

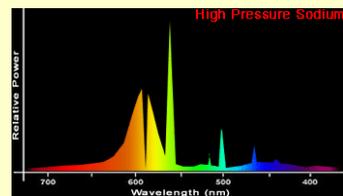

- Light sources (lightning, fertilization, sunbeds, photomedicine...)
- concentration determination (flame photometer)
- luminescence spectroscopy
- luminescence microscopy
- dosimetry (see later)
- archeology
- architecture
- safety control ... many more

Luminescent light sources

Metal vapor lamps

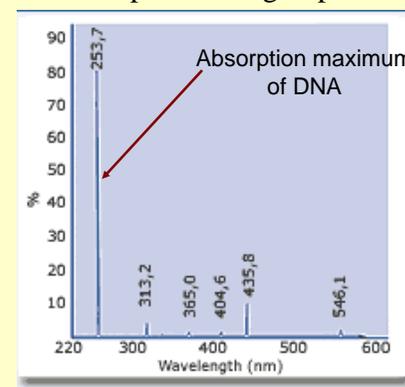

Low-pressure Na-vapor lamp

High-pressure Na-vapor lamp

Low-pressure Hg-vapor lamp

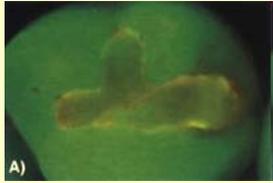

Emission spectrum

„germicid lamp”

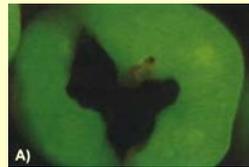

Application in dental medicine

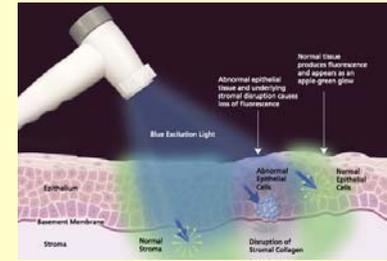

Red fluorescence indicates the activity of identifies cariogenic bacteria

Auto-fluorescence of teeth. When teeth are illuminated with high intensity blue light they will start to emit light in the green part of the spectrum.

amalgam restoration

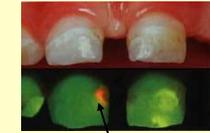

Healthy and malignant tissues different fluorescent properties

Tooth native and fluorescent image

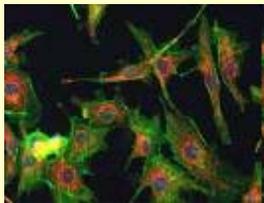

Teeth native and fluorescent images

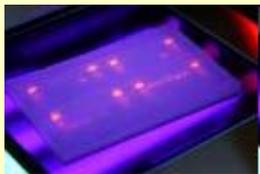

Active caries

caries

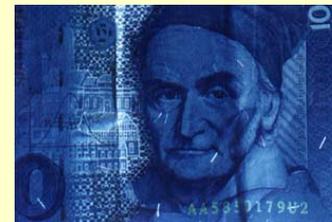

Luminescent microscopy

Laboratory application in many ways

And more...
