

Medical biophysics 2.

Biomechanics Biomolecular and tissue elasticity

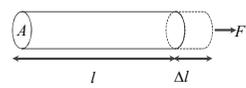

Zsolt Mártonfalvi

Department of Biophysics and Radiation Biology
Semmelweis University
Budapest

Basics of mechanics

Hookean elasticity

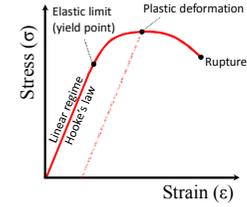

$$\frac{F}{A} = E \frac{\Delta l}{l}$$

F = force
A = cross sectional area
l = rest length
Δl = extension

F/A = σ = stress (N/m² = Pa)
Δl/l = ε = strain (dimensionless)
E = σ / ε Young's modulus (Pa)

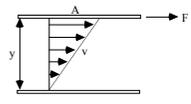

Stress-strain diagram

Linear region
Hooke's law
Elastic limit (yield point)
Plastic deformation
Rupture

Stress (σ)
Strain (ε)

Viscosity

$$\frac{F}{A} = \eta \frac{\Delta v}{\Delta y}$$

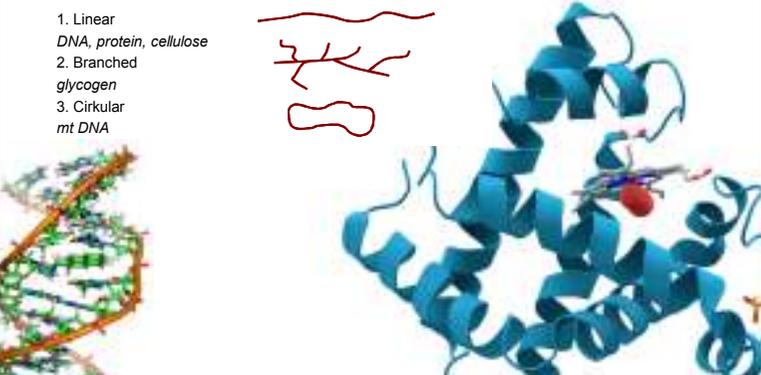

F = shear force
A = fluid surface
η = viscosity
y = distance between surfaces
v = flow velocity

F/A = shear stress
Δv/Δy = velocity gradient (strain)

Biomolecules are polymers

Common feature: Linear primary structure (protein, DNA)
Strong bonds between monomers (covalent)
Weaker interactions between distant region of polymer chain

1. Linear
DNA, protein, cellulose
2. Branched
glycogen
3. Circular
mt DNA

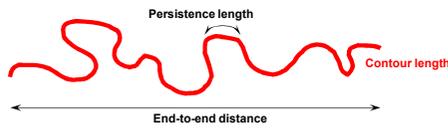

What is the shape of polymers?

Parameters to describe the shape of a polymer

AFM image of dsDNS

Persistence length
Contour length
End-to-end distance

Contourlength (L): Full length of the chain

End-to-end distance (R): Distance between chain termini.

Persistence length (l): describe the persistence of chain orientation.

$\langle \cos \varphi \rangle = e^{-\frac{\Delta s}{l}}$

Shorter persistence length polymers are more flexible.

The shape of a biopolymer resembles the „random walk”

„Random” -walk

“Square root relation”:

$$\langle R^2 \rangle = Nl^2 = Ll$$

$\langle R \rangle = \sqrt{Ll}$

R = end-to-end distance
 r_i = elementary vector

*To double the average end-to-end distance of an entropic polymer, the contourlength need to be increased four times.
 Shorter persistence length results in a more flexible polymer, which folds into a compact state with shorter end-to-end distance.*

7.th lecture: Diffusion $\Rightarrow \langle x \rangle = \sqrt{2Dt}$

Biopolymer classification based on flexibility

l = persistence length
 L = contour length

Rigid $l \gg L$	Microtubule			
Semiflexible $l \approx L$	Mikrofilaments			
Flexible $l \ll L$	DNA			

aktin
tubulin

Are biopolymers flexible?

Yes, but Hooke's law is not valid! Non-linear elasticity.

Entropic elasticity

Thermal energy ($k_B T$) excites bending movements in the chain

↓

The chain's disorder (entropy) increases

↓

The chain shortens

Force is needed to stretch an entropic chain

$$F \sim \frac{k_B T}{l} \cdot \frac{R}{L} + \left(\frac{R}{L}\right)^\alpha$$

F = force
 l = persistence length
 k_B = Boltzmann constant
 T = absolute temperature
 L = contour length
 R = end-to-end distance
 R/L = relative extension

Nonlinear elasticity

Force (pN)

Relative extension

Hookean elasticity

Increasing Persistence length

How to stretch single molecules?

Optical tweezers

Laser beam

Microscope objectives

microbead

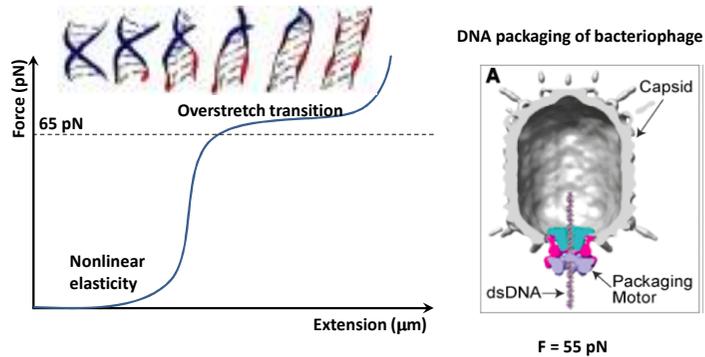

Movable micropipette

Molecule (DNA, protein...)

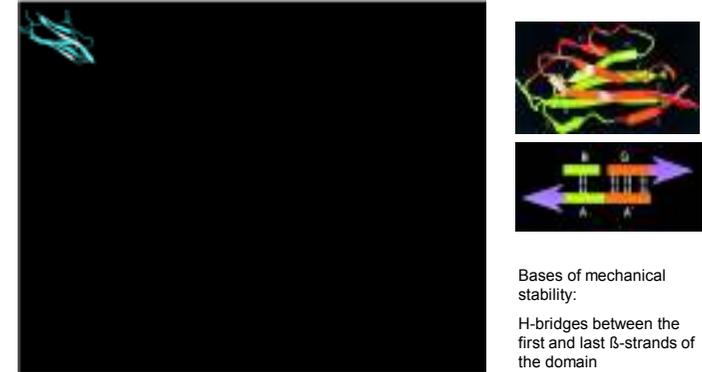

Laser beam

<http://glass.phys.uniroma1.it/dileonardo/Applet.php?applet=TrapForcesApplet>

Stretching dsDNA with optical tweezers

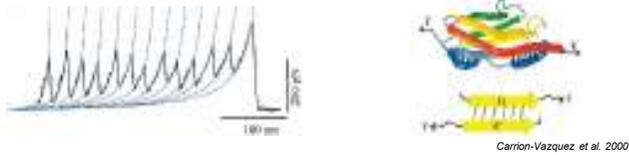

Unfolding of globular protein with force

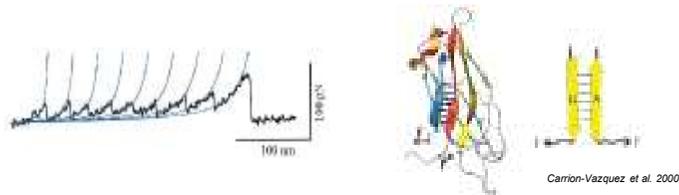

Tertiary structure determines the mechanical stability of a protein

H-bridges perpendicular to the force: High stability, unfolding forces above 200 pN

H-bridges parallel to the force: low stability, unfolding forces under 100 pN

600 seconds brake

Biomechanics at the cellular level

Forces in tissues result from:

- cell-generated tension
- fluid flow
- stretch
- hydrostatic/osmotic pressure

Cellular dimensions:
Length: μm Force: pN
 $1\text{Pa} = 1\text{pN}/\mu\text{m}^2$

Forces at work in tissues

Reference Compression Tension Shear

Forces as mechanical signals:

- highly directional
- decay: $1/r$
- convey complex information in 3D
- communication over long range
- rapid regulation
- no diffusible intermediate

Soluble (chemical) signals:

- diffuse rapidly (not directional)
- decay: $1/r^2$
- shorter range of communication
- need of intermediates

Blood Brain Lung Endothelial tissue Stromal tissue Smooth m. Skeletal m. Cartilage Bone Enamel

Elastic modulus (Pa)

Increasing stiffness

Hard tissues

Tooth tissues

Bone

Major components:
collagen (organic),
apatite (inorganic)

Soft tissues

Skeletal muscle

Passive mechanics: titin, desmin
Active mechanics: actin, myosin

Elastic artery

collagen, elastin

Ligament

Tendon

Cartilage

Collagen, proteoglycans (water)

Flashback: What did you learn about ultrasound propagation....?

What is the speed of sound in different tissues?

Acoustic properties of various tissues are determined by their flexibility

	E (GPa)	κ (GPa ⁻¹)	c_{sound} (m/s)
Bone	18	0.05	3600
Muscle	7×10^{-5}	0.38	1568

$$c_{\text{sound}} = \frac{1}{\sqrt{\rho \cdot \kappa}}$$

$\kappa = \frac{-\Delta V/V}{\Delta p}$ strain stress

compressibility

Greater Young's modulus, faster sound speed

Bone

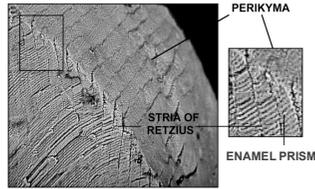

Due to the different structure of bone tissue along the cross section of long bones, the **Young's modulus distribution is anisotropic**. Denser cortical bone has greater Young's modulus vs. the trabecular bone.

Young's-modulus: 5-20 GPa
Decalcified bone (acid treatment): flexible
Removal of organic compounds (heating): brittle

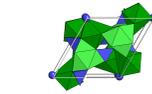

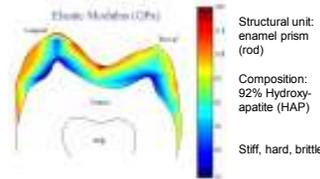

Calculation:

Bone has a Young's modulus of about 18 GPa. Under compression, it can withstand a stress of about 1.60×10^8 Pa before breaking. Assume that a femur (thigh-bone) is 46 cm long, and calculate the amount of compression this bone can withstand before breaking.

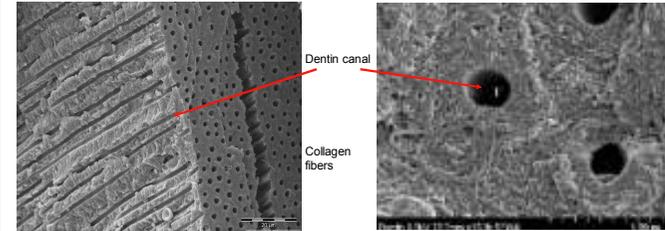

Tooth enamel

The hardest material in human body

Dentin

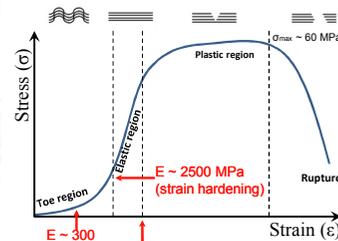

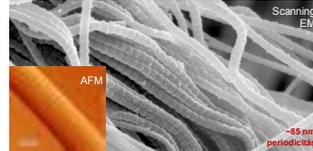

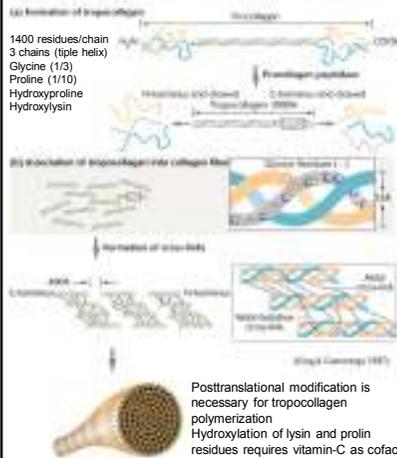

Composition: 35% organic material (collagen) + water, 65% hydroxy-apatite

Structure: collagen matrix with attached hydroxy-apatite crystals

Biomechanics: moderately hard, very strong and tough and flexible

Collagen

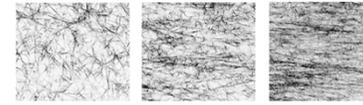

Moderately elastic and tough, but soft

Collagen responses to force

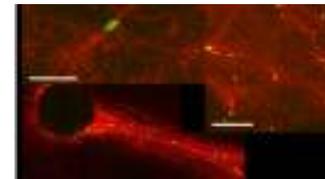

(forces in the extracellular matrix)

Stretched collagen gel

Individual fibers in a stretched collagen matrix align to the direction of stress. The structural alignment of the extracellular matrix depends on the stress.

Cells in collagen matrix

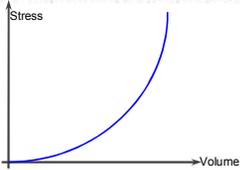

Green: nucleus
Red: collagen fibers

The presence of cells in a collagen network induces stress variations and modifies the network texture in its vicinity.

Biomechanics of elastic arteries

Non-linear elasticity

Strain is not linearly proportional to stress.

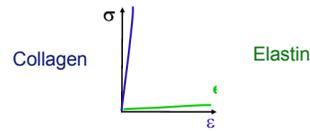

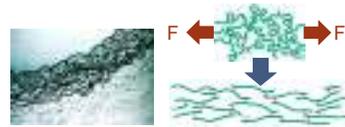

Determinants of vascular elasticity:

- Elastin
- Collagen
- Smooth muscle

Implications of vascular elasticity:

- Storage of potential (elastic) energy
- Dampening of pressure pulses
- Constant flow rate

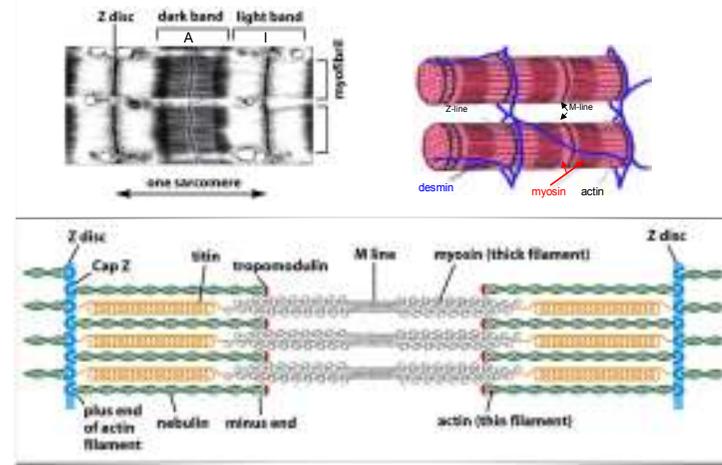

$E = 300 \text{ MPa} \dots 2\,500 \text{ MPa}$	$E = 0,1 \text{ MPa} \dots 0,4 \text{ MPa}$
$\sigma_{sz} \approx 60 \text{ MPa}$	$\sigma_{sz} \approx 0,6 \text{ MPa}$
$\epsilon_{sz} \approx 0,08$	$\epsilon_{sz} \approx 3$

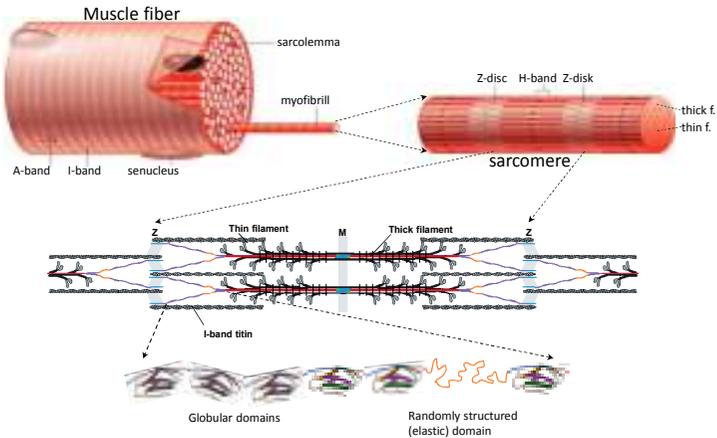

↓ strength ↓ elasticity

Sarcomere

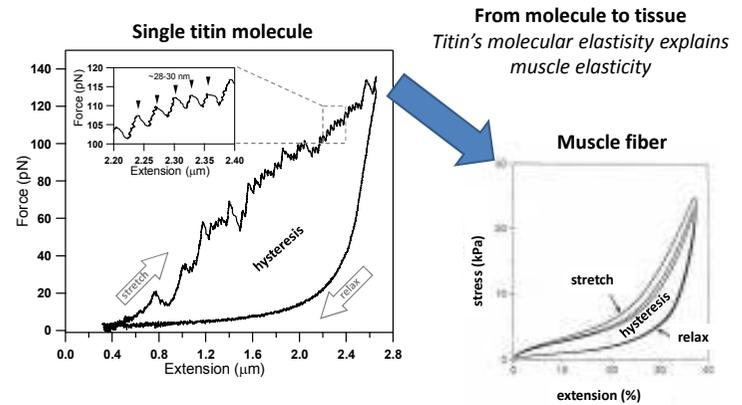

structural unit of skeletal muscle

Titin: elastic filament of the sarcomere

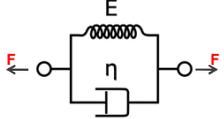

Titin is the main determinant of muscle elasticity

Visco-elasticity

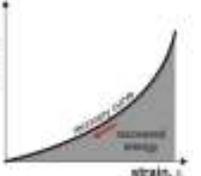

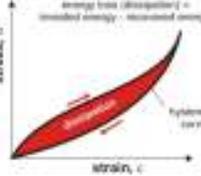

(mechanical model)

model: parallel connection of a spring and a dashpot (Kelvin-body)

Spring: ideally elastic (Hooke) body

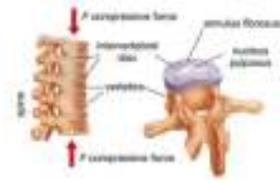

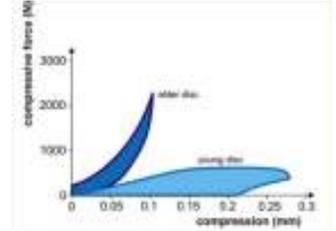

Dashpot: ideally viscous (Newton) body

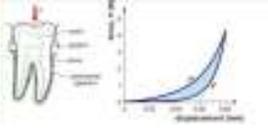

Visco-elasticity

(examples)

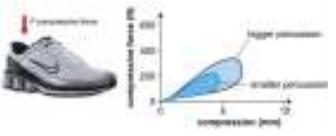

Intervertebral disc

Periodontal ligament

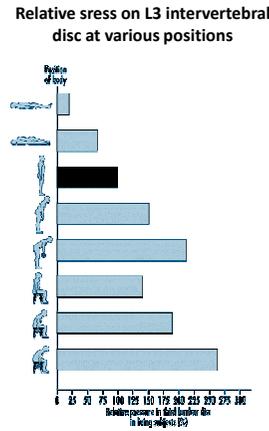

Running shoe

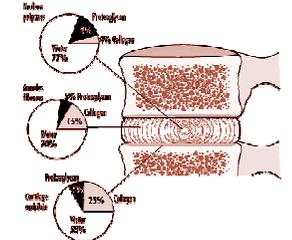

Example I: Consequences of increased mechanical stress on intervertebral discs (*discus hernia*)

Relative stress on L3 intervertebral disc at various positions

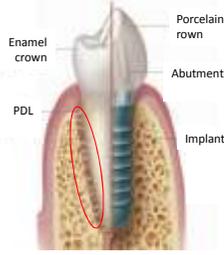

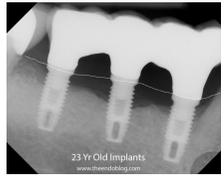

Source: Medial Flow Research 1992.

Example II: Implants vs natural tooth

PDL makes the difference!

23 Yr Old Implants
www.bonafideimplants.com

Absence of PDL result in :

- loss of masticatory force perception
- loss of visco-elastic (damper) effect
- loss of force sensory mechanisms
- No implant movement

Implant is in direct contact with bone tissue

↓

Increased compressive stress

↓

Bone loss (0.2 mm / year)
Loss of gingival height

Implants ↔ Root Canal Treatment

Calculations

To stretch a relaxed biceps muscle 3 cm requires a force of 25 N. To do the same stretch of a contracted muscle at its maximal tension requires a force of 500 N. Find the Young's modulus for both relaxed and tense muscle tissue. Assume the biceps is a uniform cylinder of length 20 cm and diameter 6 cm. (59 kPa, 1.18 MPa)

Collagen fiber is stressed with 12 N force. The cross-sectional area of the fiber is 3 mm², its coefficient of elasticity is 500 MPa. Give the percentage of relative extension. (0.8 %)

The length of an elastic thread used in orthodontics is 6 cm, its cross-sectional area is 1 mm², its coefficient of elasticity is 5 MPa. We extend the thread with 40 %. How large is the retracting force and what is the amount of elastic energy stored in the thread? (F = 2 N, E = 24 mJ)
