

Physical Foundations of Dental Materials Science

2.

Structure of matter

Liquids, solids, liquid crystals

Highlights:

- ❖ Viscosity
- ❖ Water and saliva
- ❖ Crystals - apatite
- ❖ Polymorphism
- ❖ Crystal defects
- ❖ Amorphous materials
- ❖ Liquid crystals (Material found in Medical Biophysics!)

E-book Chapters: 4, 5
Medical Biophysics I/3.4.2.

Problems:
Chapter 1.:
22, 23, 32, 33, 34, 35

States of matter - Phases

	 T		
	<div>solid</div> <div>liquid</div> <div>gas</div>		
definite volume	+	+	-
stable shape	+	-	-

Fluids

indefinite shape:

Shape does not recover after deformation, lack of restoring forces.

versus

Solids

definite shape:

Shape recovers after deformation, due to restoring forces.

Fluids

particle movement versus inter-particle bonds

Short range, dynamic order

isotropic

Viscosity (η) \longleftrightarrow [Fluidity ($1/\eta$)]

(later: Hagen-Poiseuille law)

Newton's law of viscosity:

$$F_s = \eta \cdot A \cdot \frac{\Delta v}{\Delta h}$$

viscosity (coefficient of internal friction)

$$[\eta] = \text{Pa} \cdot \text{s}$$

Another form of Newton's law:

$$\sigma_{shear} = \eta \cdot g_v$$

shear stress

velocity gradient

$$\sigma_{shear} = \eta g_v$$

Which one has higher viscosity?

$$\eta < \eta$$

Rotational viscometer:

Figure schematically shows the structure of a rotational viscometer. The inner cylinder is still and the outer is rotated. The radius of the outer cylinder $R = 2.2$ cm, the inner cylinder $r = 1.2$ cm. The cylinder's height is $h = 10$ cm. The tested liquid between cylinders is glycerine. Layer thickness is $\Delta y = R - r = 1$ cm. Calculate the force that is necessary for uniform rotation of the cylinder does 90 revolutions per minute? (viscosity of the glycerine $\eta = 1500$ mPas. The flow is laminar.)

Newton's law of viscosity:

$$F_s = \eta \cdot A \cdot \frac{\Delta v}{\Delta h}$$

$\eta \sim$ is the slope
(constant)

material	η (mPas)
air	0,019 (20° C)
water	1 (20° C)
saliva substitute (USA patent)	2–10
glycerol	1500 (20° C)
ethyl methacrylate monomer	0,5 (25° C)
ethylene glycol dimethacrylate monomer	3,4 (25° C)
zinc phosphate	95 000 (25° C)
zinc oxide -eugenol	100 000 (37° C)
silicone	60 000-1 200 000 (37° C)

- η depends on:
- material quality
 - temperature

η depends on: **1.** shear forces/velocity gradient

liquids

Newtonian fluids

i.e. water, oil

Non-Newtonian fluids

pseudoplastic

i.e. saliva, blood
polycarboxylate cements,
elastomer impression
materials

dilatant

i.e. dental composite resins

Bingham-fluid:

η depends on: 2. time of mechanical stress

Thixotropic fluid:

some dental impression materials

Rheopex fluid:

Not to confuse them with dilatant and pseudoplastic fluids!

Saliva

saliva
substitutes:

Solid materials

(crystal = solid body)

crystalline

amorphous

single crystal

polycrystalline

single crystal

polycrystalline

crystallites
or grains

anisotropic \leftrightarrow isotropic

Apatite

OH⁻ : hydroxyapatite
F⁻ : fluorapatite

Dentin, bone: 20-60 nm x 6 nm crystals

Enamel: 500-1000 nm x 30 nm crystals

Polymorphism

Examples:

SiO_2

tridymite

cristobalite

quartz

carbon (C)

fullerene

Tin (Sn)

polymorphism of elements = **allotropy** 16

Crystal defects

- point defects

- thermal defect

- vacancy (Schottky-defect)

- interstitial defect

- Impurity (dopant)

- substitutional impurity atom

- interstitial impurity atom

(alloys !!)

$$n_{S_{\circ}} = N \cdot e^{-\frac{\epsilon_s}{kT}}$$

No. of Schottky-defects

Frenkel-defect

Frenkel-pair

0.9 eV energy is necessary to produce a vacancy in copper.

a) How many percent is the ratio of vacancies in the crystal at 1000°C?

$$n_S = N \cdot e^{-\frac{\varepsilon_s}{kT}}$$

Generation and diffusion of point defects:

Thermal defects in biomolecules

Academy Artworks

$$n_{S_{\circ}} = N \cdot e^{-\frac{\epsilon_s}{kT}}$$

No. of broken H-bonds

- Line defects

- edge dislocation
- screw dislocation

edge dislocation

screw
dislocation

- planar defects

dislocations in
titanium alloy

Lattice defects strongly influence the properties!

i.e. optical properties

NaI

NaI + Tl

Scintillation crystals for detecting X-ray and gamma rays.

Emits light when irradiated by X-ray!

i.e. mechanical
properties

i.e. chemical
properties

Lower solubility in
acids.

i.e. electronic
properties

doped semiconductors

Amorphous materials = glass, glassy materials

- short distance order
- many defects
- no defined shape (flows)
(extreme high viscosity, thus flow is extremely slow)
- hard materials
- isotropic

i.e. glass, synthetic resins, wax, asphalt,

crystalline SiO_2

amorphous SiO_2

• Si • O

pitch drop experiment

Liquid crystals

- anisodimensional molecules
- mesophasic
- partially ordered structure
 - Translational order
 - Orientational order
- fluid
- optically anisotropic
- structure can change according to environment
 - temperature can change the order: *thermotropic liquid crystals*
 - concentration: *lyotropic liquid crystals*

smectic

translational +
orientational order

nematic

only orientational
order

cholesteric

only orientational order
(twisted nematic)

Contact thermography (thermo-optical effect)

LCD

(electro-optical effect)

Lyotropic liquid crystals

Shape of phospholipid molecule

lamellar

liposome
